Abstract
This study is investigating about marine currents provided electrical energy through the numerical model. The objective of this study is to know the power available distributions in the Manado Bay, North Sulawesi, Indonesia. The Manado Bay was width 2200 m with 79 m of depth. In computation, we are made grids in x and y horizontal were 7 m respectively, also for z vertical of four layers. The results shown that the power available distributions in the Manado Bay at 0.1 Sv were 0.00-20.00 kW/m² when low tide currents and when high tide currents were 0.00-105 kW/m². The values will enable for marine currents power plant in the Manado Bay to future.

Keywords: numerical model, marine currents, the Manado Bay, power available

1. Introduction
Numerical methods are one completion to determine the power available in Manado Bay. Already many researchers are investigating on numerical methods for ocean currents such as Casulli and Cheng in [1] that study on numerical method in San Francisco Bay, California and Lagoon of Venice, Italy. They simulated flooding and drying of tidal mud-flats in conjunction by 3D flows. Clement, et al., in [2] that developed numerical models in Bering Sea in North Pacific which have investigated the short-term marine circulation and flux in a small geographic region. Zarrati and Jin in [3] developed the mathematical model for 3D simulation into multi-layer model. Their models were able to predict diverse three-dimensional flow conditions through the velocity distribution and secondary flows. Rompas and Manongko [4] have studied on velocities of marine current in Bunaken Strait, North Sulawesi, Indonesia by numerical simulation. Draper, et al., [5] simulated energy potential of a tidal near a coastal headland using 2D depth averaged numerical model. Numerical experiments of tidal currents near New River inlet, NC, USA are conducted by Chen, et al., [6]. The Reynolds-averaged Navier-Stokes (RANS) equations as the basic equations used to solve numerical modeling [7-9]. The numerical models of tidal currents are developed such as in a coastal ocean (Maine Gulf, Fundy Bay, Minas Passage, and Minas Basin in North America) with subgrid approximation [10], in the Gold Coast Seaway area, Gold Coast, Australia [11] with simulations of flow, wave, and sediment transport. The evolution of tidal creek has studied by Gu, et al., [12]. Elzalabani, et al., [13] have presented the mathematical modeling and simulation tidal current energy that can be modeled as a stream of harmonics and applied in building the tidal barrage across a bay.

In this study, we have used a numerical model that developed from [1-3]. Also, we want to investigate the power available distributions in the Manado Bay, North Sulawesi, Indonesia which influenced by Singkil river (refer to Figure 3).

2. Theory
2.1. Mathematical Model
The governing equations used to get the distributions of the power available from basic RANS equations [14]. The model of equations become:
\[
\begin{align*}
\frac{\partial \bar{u}}{\partial t} + \bar{u} \frac{\partial \bar{u}}{\partial x} + \bar{v} \frac{\partial \bar{u}}{\partial y} + \bar{w} \frac{\partial \bar{u}}{\partial z} &= -g \frac{\partial \eta}{\partial x} + \text{div} \left( \nu \text{grad} (\eta) \right) + \frac{f_{\text{cor}}}{\rho} \\
\frac{\partial \bar{v}}{\partial t} + \bar{u} \frac{\partial \bar{v}}{\partial x} + \bar{v} \frac{\partial \bar{v}}{\partial y} + \bar{w} \frac{\partial \bar{v}}{\partial z} &= -g \frac{\partial \eta}{\partial y} + \text{div} \left( \nu \text{grad} (\bar{v}) \right) - \frac{f_{\text{cor}}}{\rho}
\end{align*}
\]
\[
\frac{\partial \bar{w}}{\partial t} + \bar{u} \frac{\partial \bar{w}}{\partial x} + \bar{v} \frac{\partial \bar{w}}{\partial y} + \bar{w} \frac{\partial \bar{w}}{\partial z} = 0
\]

where \( \bar{U} (x,y,z,t) \), \( \bar{V} (x,y,z,t) \), and \( \bar{W} (x,y,z,t) \) are the velocities in horizontal directions of \( x, y, \) and \( z \)-direction respectively, \( \eta(x,y,t) \) is the elevation of free surface, \( t \) is the time, \( \nu_{\text{eff}} \) is an effective diffusion taking of account turbulent viscosity and dispersion, \( \nu_{\text{eff}} = \nu + v_t \), \( f_{\text{cor}} \) is the Coriolis parameter, assumed to be constant, and \( g \) is the gravity.

### 2.1.1. Turbulence Model
The equation of turbulence that used was turbulent viscosity from the mixing-length model [15, 16] as follow:
\[
v_t = \left( l_h^2 \left[ \left( \frac{\partial \bar{u}}{\partial x} \right)^2 + 2 \left( \frac{\partial \bar{v}}{\partial y} \right)^2 + \left( \frac{\partial \bar{w}}{\partial z} \right)^2 \right] + l_v^2 \left[ \left( \frac{\partial \bar{u}}{\partial z} \right)^2 + \left( \frac{\partial \bar{w}}{\partial x} \right)^2 \right] \right)^{1/2}
\]
where \( l_h \) and \( l_v \) are horizontal and vertical mixing length scales respectively.

### 2.1.2. Boundary Conditions
In the numerical study here, the boundary conditions need to be set as [14]: by the bottom, by the surface of the water [17], by boundaries which can be vertical impermeable structures (wall), and by boundaries in the open sea [18].

The power available in the Manado Bay, we can be obtaining from equation [19, 20]:
\[
P = \frac{1}{2} \rho (v)^3 10^{-3}
\]
where \( P \) in kW/m2, \( v \) is \( \sqrt{u^2 + v^2 + w^2} \) (m/s) and \( \rho \) is density of water (kg/m³).

### 2.2. Numerical Model
The numerical method that used was semi-implicit finite difference for the 3D in Equation (1), (2), and (3) was used by: [1], [3], [12], [15], and [21-23].

Figure 1 shows choices adopt in the vertical direction. The velocities are defined on the edge of the mesh, we guessed virtual meshes to write the limiting conditions with the walls, and we decorate the free surface with the grid.

The generally, we can be written semi-implicit discretization in Equation (1) and (2) in the compact matrix form [1] as follow:
\[
A^n_{i+1/2,j} U^n_{i+1/2,j} = G^n_{i+1/2,j} - \frac{At}{\Delta x} (\eta_{i+1,j}^{n+1} - \eta_{i,j}^{n+1}) \Delta z_{i+1/2,j}^n
\]
\[
A^n_{j+1/2} V^n_{j+1/2} = G^n_{j+1/2} - \frac{At}{\Delta y} (\eta_{j+1}^{n+1} - \eta_{j}^{n+1}) \Delta z_{j+1/2}^n
\]

Then, the velocity vertical in Equation (3) becomes:
If we discretize Equation (5), then the power available becomes:

\[
P = \frac{1}{2} \rho \left( v_{ij}^{n+1} \right)^2 \times 10^{-3}
\]  

(9)

where \( P \) is the availability power in the Manado Bay (kW/m²) and \( v_{ij}^{n+1} = \sqrt{u^{n+1} + v^{n+1} + w^{n+1}} \) is velocity resultant with \( u = \frac{1}{2} (u_{i,j}^{n+1} + u_{i,j+1}^{n+1}) \), \( v = \frac{1}{2} (v_{i,j}^{n+1} + v_{i,j+1}^{n+1}) \) and \( w = \frac{1}{2} (w_{i,j}^{n+1} + w_{i,j+1}^{n+1}) \) are scalars, respectively.

3. Method

Figure 2 shows flow chart for solution of a numerical model in calculating the velocities of \( u, v \) and \( w \) and power available in the Manado Bay. The “calculate components of the velocities (u, v and w) and power available” symbol are show a process for calculating of horizontal velocities \( \mathbf{u} \) (Equation 6) and \( \mathbf{v} \) (Equation 7) with a linear three-diagonal, whereas for calculating velocity vertical \( \mathbf{w} \) use Equation (8). Finally, calculating the power available where the calculation used Equation (9). The “n” symbol shows the quantity of calculating with iteration do-process until maximum iteration \( T_{\text{max}} \). The “\( T > T_{\text{max}} \)” symbol is the process to execute determination when the iteration has been greater than maximum iteration, if no then process will be go to “n” for continue to calculate again, and if yes then it go to “finish”.

The position of Manado Bay in Indonesia and numerical area are located in the Sulawesi Sea with approximately 300 km² of the area (Figure 3) and width of about 2.2 km between Bunaken Island and Sulawesi Island, and down to 79 m deep.

We are made two types of simulations in 3D-simulations with one discharge. There are four layers to deep. In calculation, there are 174 x 318 mesh in \( x, y \) directions with \( \Delta x = \Delta y = 7 \) m. Also, we are used four vertical layers and the integration time \( \Delta t = 0.4 \) sec (Table 1), and discharge is 0.1 Sv (1 Sv = 10⁶ m³/s). Figure 4 illustrates the bathymetry 3-D and 2D of the Manado Bay which used for numerical simulation.

Tide predictions were computed based on the Admiralty method using Harmonic Constants taken from the Indonesia Sailing Direction and the results of the Hydro-Oceanographic surveys. Information about tide is needed for the safety of navigation as mention in navigational Indonesia regulation number 21, 1992 [24]. Hourly heights of tide of 95 stations
in Indonesia are given for whole period in one year. Time used in local standard time. Predictions refer to Chard Datum of Low Water Spring. Height should be added to charted depths, unless preceded by minus sign (-) then they should be subtracted. Water heights are given in Meter. It is pointed that though the prediction in the tide tables, in substance gives the actual movements of tide.

4. Results and Discussion

We can see that the power available distributions when high tide currents (Figure 6b) at in front of the Singkil river downstream (Figure 4b) where around 80-105 kW/m² bigger than the other area in around that of 1-60 kW/m². It caused by existence of manger and average depth in the place of ~5 m. Also, in West area, especially at centre area where power availabilities around 16-20 kW/m². Whereas in North area where the power available still less unless in South area about 30-50 kW/m². Figure 5 shows the tide predictions for 37 days from on 16 January to 21 February 2014 [24]. Predictions refer to Chart Datum 1.2 m under Mean Sea Level (MSL). The type of tides is mixed, mainly semidiurnal and some of that are diurnal.

If we see in Westside (left hand) where there are power availabilities biggest around 10-15 kW/m². When low tide currents (Figure 6. a) at in front of the Singkil river, East-North, and East-South, where around 15-20 kW/m². Whereas at enter channel in Singkil river of 0.5-8 kW/m². It is caused due to the confluence of the river and the marine currents, also, the flow of river water to move freely into the sea with an average depth of 2 m.
Figure 6. 2D-Simulated distributions of the power available when low tide currents (a) and high tide currents (b) in the Manado Bay

Figure 7. 3D-Simulated distributions of the power available when low tide currents (a) and high tide currents (b) in the Manado Bay

The distributions of the power available when low and high tide currents in the Manado Bay (3D-simulation) at discharge 0.1 Sv respectively showed in Figure 7. Tide currents very influence to the power available which very big at high tide current [25-27]. When low tide currents, the distributions were 0.00-20.00 kW/m² and 0.00-105.00 kW/m² when high tide currents in the Manado Bay.

4. Conclusion

Study on marine current in the Manado Bay, North Sulawesi, Indonesia through a numerical model has been successfully accomplished. The maximum of power available at discharge of 0.1 Sv when low and high tide currents were 20 and 105 kW/m² respectively. The results will be enabling to design the turbines that used in the marine current power plant in Manado Bay in the future.
